

SYSTEM DIAGRAM · OUTREACH & FEEDBACK ASSISTANT

One message, start to finish

The app has no automatic trigger and no channel of its own — every loop starts and ends with an account manager, and WhatsApp sits entirely outside the system. What the software contributes is the middle: two gates that read shared history before a draft is even offered, a click-to-chat link that opens the message pre-filled instead of asking anyone to copy it, and a queue that a rule — not a click — puts things into.

A message's full lifecycle: an account manager starts it, two gates check history before Gemini is asked for a draft, a click-to-chat link opens WhatsApp pre-filled so sending is one press rather than a copy-paste, the reply still comes back by hand, and resolving a callback writes back into the same log the first gate reads — so next time, the gate sees it.

— next step in this message's path - - - reads or writes shared history - - - leaves the app — a human bridges it □ a rule that can block the flow ○ a CSV file on disk

■ Why a human still bridges it twice

The app has no WhatsApp Business API connection, so it cannot send a message or read a reply on its own. **Sending** is now a click-to-chat link (*wa.me*) — the chat opens with the draft already typed in, so the only manual act left is pressing Send. **Logging the reply** is unchanged: there is no read access to WhatsApp, so the account manager still types what the client said into "Add feedback" by hand. A real WhatsApp Business API would close that second gap; it needs Meta business verification and per-conversation cost that a course prototype doesn't carry.

■ Why the gates read history, not a checkbox

The **review gate** and **cooldown gate** both query the same two files the bottom half of the loop writes to — a client's own feedback record decides whether they can be asked for a public review, and their own send history decides whether they're due a message at all. Neither can be bypassed by a rushed click, because neither is a click to begin with.

- rules & data layer – 69 tests passing
- escalation queue, resolve, cooldown – run live in-browser
- wa.me link – format verified, matches WhatsApp's own spec
- Gemini draft quality – not yet seen with a real key
- click-through to WhatsApp – not yet clicked by a human
- reply logging – still fully manual, by design
